The author is kindly please add the book to your own library via the button below.Mocality: a self-organizing and personally controlled tutoring portal. We developed a web-based tutoring portal to help students improve their academic results at least at the same level as the one achieved by a tutor. Students are able to place requests for help from their teacher, and Tutor Vision provides an automated answer to these requests, with an analysis of the cause of the problem and suggestions for a solution. A high percentage of requests have a positive answer, resulting in a significant increase in student satisfaction.Q: Why is invoking the erase\_copy\_if algorithm a faster alternative than explicitly calling the erase-assign algorithm? I noticed that there's a problem when you try to use erase-assign to erase elements from the middle of a std::vector. The problem is that it's hard to ensure that the elements on either side that are not deleted are properly shifted, which is a very cheap operation. (That is, in contrast to comparing elements, the overhead of shifting pointers is considered to be near-zero.) So I tried a number of alternative algorithms, including erase-copy-if (which does the same thing, but moves elements to the start of the vector). However, I noticed that when I use std::vector::erase\_copy\_if(iterator first, iterator last) the compiler was able to detect the absence of shift operations, and opted to use a few shifts. I thought that a variation on this algorithm that removes elements by comparing elements might be faster. So I tried
